Clogging of steam generators (SGs)

Clogging of SGs is a complex multiphysics phenomenon that occurs following long operational periods in pressurized-water reactors (PWR) of the French nuclear fleet → undermines performance & weakens the structures → may require chemical cleanings

Figure: PWR scheme, and example of video examination during a PWR outage (© IRSN, EDF)

Clogging of SGs

- No state-of-the-art model allowing for ground insights on diagnosis and prognosis of clogging rate *τ_c* → very hard to model & challenging to create reproducible lab experiment for model validation + not a lot of literature [Srikantiah and Chappidi, 2000; Prusek et al., 2013; Girard, 2014; Yang et al., 2017]
- ► Available scarce video field data as well as indirect measurements → allow to construct data-driven regression algorithms [Pinciroli et al., 2021] ≈ not enough data to have robust predictive models
- ► Another tool is the physical clogging model developed by [Prusek et al., 2013] → subsequent numerical model THYC-Puffer-DEPO [Feng et al., 2023] ≈ lack of enough trustworthy field data for precise validation

Introduction

- ► Industrial engineering systems such as airplane blades, concrete structures in bridges, components in nuclear reactors → subject to complex physics and regular loads → degrade over time, need maintenance or replacement especially in critical applications
- Degradation level t → δ(t) for an industrial system → objective is to predict remaining useful life (RUL) [Biggio and Kastanis, 2020] for a fixed threshold D ∈ ℝ₊:

$$\mathsf{RUL}(D) = \underset{t_1 < t \le t_N}{\operatorname{argmin}} \{\delta(t) \ge D\}$$
(1)

- Usually relies on physics-based simulation codes, and/or data driven methods
- ► RUL prediction with each individual approach is not robust → high level of uncertainty & individual predictions not fully reliable

Introduction

Available tools:

- ▶ Physics-based computer simulation model $g : \mathcal{X} \subset \mathbb{R}^d \to \mathbb{R}^N$ with prior uncertainty on input variables $\mathbf{X} = (X_1, \dots, X_d) \sim \mu_{\mathbf{X}} \to$ one input value \mathbf{x}_0 gives the trajectory $g(\mathbf{x}_0) = (g(t_1, \mathbf{x}_0), \dots, g(t_N, \mathbf{x}_0))$ where $\operatorname{pr}_{\ell} \circ g(\mathbf{X}) := g(t_{\ell}, \mathbf{X})$ approximates $\delta(t_{\ell})$
- Surrogate modeling strategy \hat{g} if code is time-costly such that \hat{g} approximates g with less computation effort
- *q* heterogeneous degradation data groups y^1, \ldots, y^q with different sizes $y^i \in \mathbb{R}^{m_i} \to$ corresponding to different time indices in \mathcal{J}_i so that $\mathcal{J} = \bigcup_{i=1}^q \mathcal{J}_i$ and $|\mathcal{J}| = m_1 + \ldots + m_q$, we suppose that:

$$\mathbf{y}^{\prime}(t_{\ell}) = \mathbf{g}(t_{\ell}, \mathbf{X}) + \eta^{\prime}_{\boldsymbol{\ell}},$$
 (2)

with $\eta_{\ell}^{i} \sim \mathcal{N}(0, \sigma_{i}^{2}) \rightarrow$ homoskedastic noise for each data group

How to fuse these tools for hybrid RUL estimation of the system?

Offline data assimilation

- A single input parameter X = x₀ produces an entire degradation trajectory g(x₀) = (g(t₁, x₀), ..., g(t_N, x₀)), which is generally not a Markov chain → cannot use data assimilation (considered state of the art hybrid method [Jouin et al., 2016])
- Scarcity of data, packed in groups → no arrival of new data points on the fly → offline data assimilation is suitable for this context, similar to Bayesian calibration of computer models
- ► The objective is to estimate the posterior distribution $\hat{p}(\theta | \mathbf{y}^1, ..., \mathbf{y}^q)$ of influential parameters $\theta \in \mathbf{X}$
- ► This enables obtaining an updated distribution for the state variable via the pushforward g#p(θ|y¹,..., y^q)
- The probabilistic RUL is determined by its conditioned cumulative distribution function:

$$\mathbb{P}(\mathsf{RUL}(D) \le t_{\ell} | \mathbf{y}^1, \dots, \mathbf{y}^q) = \int_{\mathbb{R}} \mathbb{1}\{z \ge D\}(\mathsf{pr}_{\ell+1} \circ g) \# \widehat{p}(\theta | \mathbf{y}^1, \dots, \mathbf{y}^q)(z) dz$$

Table of contents

- 1. Introduction
- 2. Methodology
- 3. Industrial application

- 4. Summary
- 5. Appendices

Methodology

Figure: Proposed 5-steps algorithm

Perform *k* iterations where $1 \le k \le d$:

1. If k = 0, assume uniform independent priors $\mu_{\mathbf{X},k} \simeq \mathcal{U}[-1,1]^{\otimes d} \rightarrow \text{generate a design of experiments } \text{DoE}_{g}^{\mu_{\mathbf{X},k}} = \{(\mathbf{X}^{(j)}, g(\mathbf{X}^{(j)}))\}_{1 \leq j \leq n}$

 Compute HSIC indices [Gretton et al., 2005] between input variables and outputs at data time instances → given data sensitivity analysis method to assess *individual* input variable influence on the output

3. If *g* is time-costly, build and validate *p* metamodels $\widehat{\boldsymbol{g}} = (\widehat{g}^{(1)}, \dots, \widehat{g}^{(p)})$ with chosen strategy \rightarrow avoid metamodeling bias with *convex aggregation* on the unit-simplex chosing $\boldsymbol{w} \in \Delta^{p-1} := \{ \boldsymbol{w} \in [0, 1]^p, \| \boldsymbol{w} \|_1 = 1 \}$, fix nominal value of $\boldsymbol{U}_{0,k} = \boldsymbol{u}_{0,k}$ by taking the mean

- 5. Compute the Kullback-Leibler divergence d_{KL} between prior distribution $\mathcal{U}(\theta_k)$ and the estimated density:
 - If *d_{KL}* > ε, update the prior μ_{X,k} by replacing marginal U(θ_k) with p̂(θ_k|y¹,..., y^q, u_{0,k}) and continue k ← k + 1
 - Otherwise, stop and obtain an updated RUL prediction by computing g#µx,k

Bayesian updating step 4

Proposition

Assume $\lambda := 1/\sigma_{\eta}^2 \sim \mathcal{G}(\frac{m}{2}, \frac{1}{2} \| \mathbf{y} - \mathbf{f}(\theta) \|^2)$ (Gamma distribution), where *m* is the number of data points in \mathbf{y} ; $\theta \sim \mathcal{U}(\theta)$, and $p(\theta, \lambda) \propto \lambda^{-1}$. Then:

$$p(\theta|\mathbf{y}) \propto \|\mathbf{y} - f(\theta)\|^{-m}$$
 (3)

Moreover, if multiple groups of data at different time-instances are considered, $\mathbf{y}^1, \ldots, \mathbf{y}^q$, with respective priors on the inverse of their standard deviations $\lambda_i \sim \mathcal{G}(\frac{m_i}{2}, \frac{1}{2} || \mathbf{y}^i - f(\theta) ||^2)$, then the generalization is:

$$p(\theta|\boldsymbol{y}^{1},\ldots,\boldsymbol{y}^{q}) \propto \prod_{i=1}^{q} \|\boldsymbol{y}^{i} - \boldsymbol{f}(\theta)\|^{-\boldsymbol{m}_{i}}$$
(4)

Proof. Bayes' theorem and simplifications.

Bayesian updating step (4)

$$p(\theta_k | \mathbf{y}^1, \dots, \mathbf{y}^q, \mathbf{u}_{0,k}) \propto \frac{1}{M} \sum_{r=1}^M \prod_{i=1}^q \| \mathbf{y}^i - \langle \mathbf{w}^{(r)}, \widehat{\mathbf{g}}(\mathbf{u}_{0,k}, \theta_k) \rangle \|^{-m_i}$$
(5)

- Use Random Walk Metropolis-Hastings (RWMH) MCMC algorithm [Sullivan, 2015] to sample from (5)
- Monte-Carlo integration using sample { w^(r)}^M_{r=1} from the Dirichlet-1_p distribution on the simplex → integrate hyperparameter
- Test convergence of RWMH chains with Gelman-Rubin test [Gelman and Rubin, 1992]
- ► Updated densities are conditioned on nominal values u_{0,k} of other d 1 input variables → future work on how to integrate uncertainty
- Use log-sum-exp trick for numerical computation

Results

- ► Computer code THYC-Puffer-DEPO, complex multiphysics [Jaber et al., 2024b], chaining of 3 codes \rightarrow allows to simulate SG clogging on entire lifespan of the asset integrating past chemical cleanings and predicting future τ_c levels
- Two data groups q = 2, corresponding to field data and regression data

Input variable	Distribution
α	$\mathcal{U}(100, 103)$
β	$\mathcal{U}(0.02, 0.025)$
ϵ_{e}	$\mathcal{U}(0.2, 0.5)$
ϵ_{c}	$\mathcal{U}(0.01, 0.3)$
d_p	$\mathcal{U}(0.5, 10.0) \times 10^{-6}$
$\Gamma_{\rho}(0)$	$U(1.0, 8.0) \times 10^{-9}$
a_{v}	$\mathcal{U}(0, 15) \times 10^{-4}$

Table: Probabilistic modeling of uncertain input variables

Results: posterior distributions

- 3 independent calibrations for scenarios after maintenances, *p* = 12 metamodels, 5 MCMC chains are launched for GR convergence test, use uniform proposal distributions
- Computing time around 40 min → 5/7 distributions are informed by the data, distinct modes for a_v

Figure: Posterior distributions of TPD clogging simulation code

Results: posterior trajectories

- 4. Summary
- 5. Appendices

Summary

- ► Presented an iterative algorithm leveraging kernel sensitivity analysis (HSIC) to identify individual influential variables and update priors → acting sequentially on each marginal to keep independence assumption for all dimensions → avoids cross-correlation in MCMC and curse of dimensionality
- Methodology works with a metamodeling step, enriched at each iteration by an optimization + aggregation of the metamodels on the refined DoEs to avoid bias in the posteriors
- The method integrates the noise uncertainty and works with heteroskedastic groups of data points
- Demonstrated the approach on industrial steam generator clogging, showing improved posterior inference and reduced RUL uncertainty
- Methodology is general and can be adapted to other industrial prognostics problems with scarce and heterogeneous data — GitHub repository

Some extensions and future work

- How to integrate uncertainty in nominal parameters u_k ?
- ► Prior work on adaptive conformal prediction for GP surrogate models validation [Jaber et al., 2024a] → to appear in Journal of Machine Learning for Modeling and Computing

$$\widehat{C}_{n,\alpha}^{J+GP}(\mathbf{X}_{n+1}) = \left[\widehat{\mathbf{q}}_{n,\alpha}^{\pm}\left\{\widetilde{\mathbf{g}}_{-i}(\mathbf{X}_{n+1}) \pm \mathbf{R}_{i}^{LOO\gamma} \times \widetilde{\gamma}_{-i}(\mathbf{X}_{n+1})\right\}\right]$$
(6)

where $R_i^{LOO\gamma}$ is the Leave-One-Out error normalized by $\widetilde{\gamma}$

- 5. Appendices

Sensitivity analysis: HSIC

- ► Hilbert-Schmidt Independence Criterion (HSIC) [Gretton et al., 2005], kernel method → evaluates sensitivity of a single-input in a given-data context, no need for surrogate models
- Theoretical result for all $i \in \{1, \ldots, d\}, k \in \{1, \ldots, N\}$:

 $\mathsf{HSIC}(X_i, g(X, t_k)) = 0 \Longleftrightarrow X_i \perp g(X, t_k) \tag{7}$

- ► The index disposes of U-stat and V-stat estimators + hypothesis testing with corresponding *p*-value → implemented in the OpenTURNS
- The normalized R_{HSIC}^2 index is better suited for interpretation:

 $\textit{\textsf{HSIC}}(\textit{\textit{X}}_{\textit{i}},\textit{\textit{g}}(\textit{\textit{X}},\textit{\textit{t}}_{\textit{k}})) = \frac{\textit{\textsf{HSIC}}(\textit{\textit{X}}_{\textit{i}},\textit{\textit{g}}(\textit{\textit{X}},\textit{\textit{t}}_{\textit{k}}))}{\sqrt{(\textit{\textsf{HSIC}}(\textit{\textit{X}}_{\textit{i}},\textit{\textit{X}}_{\textit{i}})\textit{\textsf{HSIC}}(\textit{\textit{g}}(\textit{\textit{X}},\textit{\textit{t}}_{\textit{k}}),\textit{\textit{g}}(\textit{\textit{X}},\textit{\textit{t}}_{\textit{k}}))))}} \in [0,1]$

► Empirical evidence suggests that R²_{HSIC} can be used confidently for variable ranking → HSIC-ANOVA decompositions also exist *but* only pathological cases create stark differences (see [Sarazin et al., 2022])

Metamodeling step 3

The metamodeling process involves:

Data generation: Using the DoE of g at n input samples {X⁽ⁱ⁾}ⁿ_{i=1} ~ μ_X, assemble the data matrix:

$$\boldsymbol{Y} = \left[\boldsymbol{g}(\boldsymbol{X}^{(1)}), \dots, \boldsymbol{g}(\boldsymbol{X}^{(n)})\right] \in \mathbb{R}^{N \times n}$$
(8)

► Dimensionality reduction: Apply a Karhunen–Loève (KL) decomposition [Sullivan, 2015] using the empirical covariance matrix $\hat{C} = \frac{1}{n} YY^{T}$. Perform singular value decomposition (SVD):

$$\boldsymbol{Y} = \boldsymbol{V} \boldsymbol{\Sigma} \boldsymbol{W}^{\mathsf{T}}, \tag{9}$$

where V contains the KL modes $\{\Phi_k\}_{k=1}^m$, and Σ holds the singular values.

Mode selection: Retain m modes to capture a prescribed variance (e.g., 99%). Project trajectories onto the retained modes:

$$\xi_k(\boldsymbol{X}^{(i)}) = \boldsymbol{g}(\boldsymbol{X}^{(i)})^\top \boldsymbol{\Phi}_k, \quad k = 1, \dots, m$$
(10)

Metamodeling step 3

- Surrogate modeling: For each mode k, construct a surrogate model \(\higkarrow k, K\) using a Gaussian process [Rasmussen and Williams, 2006] with identical prior mean and kernel for all modes
- Reconstruction: Reconstruct the full trajectory using the surrogate models:

$$\widehat{g}(\mathbf{X}) = \sum_{k=1}^{m} \widehat{\xi}_k(\mathbf{X}) \Phi_k$$
(11)

$$\widehat{g}^{\text{agg}}(\mathbf{X}) = \sum_{i=1}^{p} \mathbf{w}_{i} \widehat{g}^{(i)}(\mathbf{X})$$
(12)

This ensures robustness by leveraging multiple models while minimizing bias
