- Clogging is a complex phenomenon happening in some steam generators (SGs) of pressurized water reactors (PWRs).
- Due to long operation times and corrosion of the secondary water circuit.
- Overtime, it can increase the risk of mechanical and vibrations on tube bundles and internal structures → affects the SG response to hypothetical transients.

Figure: Example of video examination during a PWR outage (© EDF).

References

- This phenomenon is controlled by chemical cleaning maintenances performed during PWR outages.
- To better address this maintenance planning, EDF R&D has worked on deploying models for enhancing the prediction of the clogging rate: τ_C .
- Two predictive models exist, a *numerical physics model* - THYC-Puffer-DEPOTHYC - and a *data-driven statistical model* - PREVICOL 900 - relying on operational data.
- The ambition of this thesis is to provide a pathway for *hybridizing* the two approaches in order to robustify the estimation.

Objective of the thesis

Clogging of steam generators, sensitivity analysis and metamodel validation

Clogging of SGs of PWRs and work motivations

Industrial use case

THYC-Puffer-DEPOTHYC (TPD)

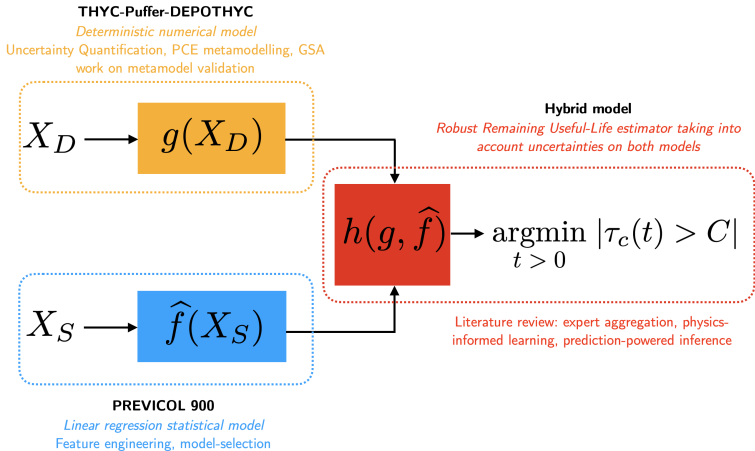

Uncertainty quantification of TPD

Sensitivity analysis on TPD

GP validation with Conformal Prediction

Summary and upcoming work

References

- Original clogging model/code: **DEPOTHYC**, developed by [Prusek, 2012] → mixed ODE-PDE system → accounts for short-time clogging evolution
- This model relies on the physical-validity of stationary thermohydraulic quantities → not guaranteed on long periods of time
- For the long-time evolution of clogging, multi-physics model: **THYC-Puffer-DEPOTHYC**, developed by [Feng et al., 2023] → takes into account chemical conditioning (pH) of the fluid.

THYC-Puffer-DEPOTHYC (TPD)

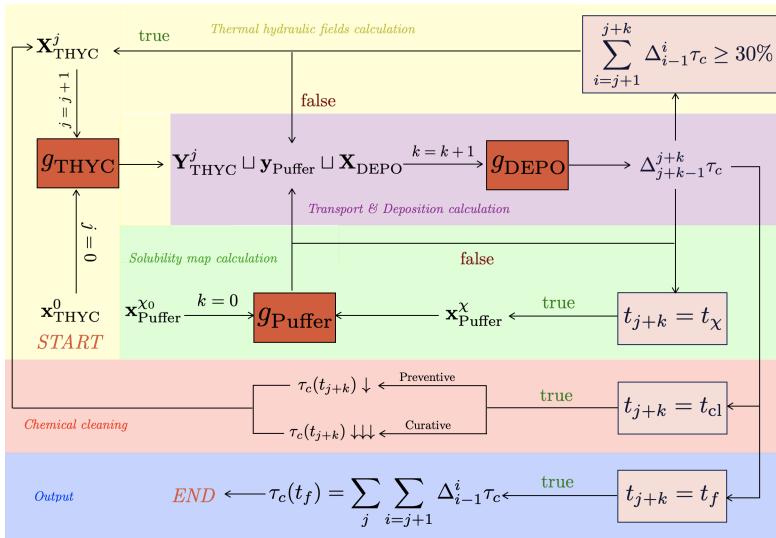

Figure: TPD architecture.

Uncertainty quantification of TPD

- Expert advice outlined the presence of uncertainty in the parameters \mathbf{X}_{DEPO} of DEPOTHYC.
- Preliminary analysis performed by [Lefebvre et al., 2023]: building of a neural-network based metamodel + estimation of Sobol' sensitivity indices + Bayesian calibration.
- However, the long-time sensitivity analysis of the THYC-Puffer-DEPOTHYC model has not yet been analyzed. This is what we address in [Jaber et al., 2023b].
- Use of metamodels requires assessing the quality of the approximation → use of validation metrics [Demay et al., 2022]
- Approach for quantifying the Gaussian Process (GP) metamodel quality with conformal prediction methods [Vovk et al., 2005; Angelopoulos and Bates, 2023] proposed in [Jaber et al., 2023a] → tested for GP metamodeling of TPD

- 4 Summary and upcoming work

- Experts outlined $d = 7$ uncertain independent input variables of the clogging module:

$$\mathbf{X}_{\text{DEPO}} = \mathbf{X} = (\alpha, \beta, \epsilon_e, \epsilon_c, d_p, \Gamma_p(0), a_v) \sim \mathbb{P}_{\mathbf{X}} = \otimes_{i=1}^d \mathbb{P}_{X_i},$$

and provided the supports of their distributions.

- $n = 1000$ crude Monte-Carlo samples on the inputs are drawn according to the distributions in the table below.
- Focus is given on the output on the hot leg (HL) of the SG at the top in Z_{max} .

Variable	Signification	Distribution
α	First empirical correlation parameter	$\mathcal{N}(101.6, 4.0)$
β	Second empirical correlation parameter	$\mathcal{N}(0.0233, 0.0005)$
ϵ_e	Porosities of the fouling deposits	$\mathcal{T}(0.2, 0.3, 0.5)$
ϵ_c	Porosities of the clogging deposits	$\mathcal{T}(0.01, 0.05, 0.3)$
d_p	Iron oxide particle diameter (m)	$\mathcal{T}(0.5, 5.0, 10.0) \times 10^{-6}$
$\Gamma_p(0)$	Initial data for solid mass transport equation	$\mathcal{T}(1.0, 4.5, 8.0) \times 10^{-9}$
a_v	Calibration parameter	$\mathcal{T}(0.1, 7.8, 12) \times 10^{-4}$

Table: Uncertain variable signification and corresponding distributions.

1000 clogging trajectories - HL at z_{max} .

Figure: Clogging simulation trajectories.

The output is a time-discretized function:

$$g_{\text{TPD}}(\mathbf{X}) = (g_{\text{TPD}}(t_1, z_{\text{max}}, \mathbf{X}), \dots, g_{\text{TPD}}(t_N, z_{\text{max}}, \mathbf{X})) \in \mathbb{R}^N, N = 75.$$

Polynomial chaos expansion (PCE) metamodel

- Here $g_{\text{TPD}} =: g$. Computing Sobol' indices \rightarrow byproduct of a polynomial chaos expansion (PCE) metamodel [Sudret, 2008].
- This means choosing an orthonormal polynomial Hilbert basis $\{\varphi_{\alpha}\}_{\alpha \in \mathbb{N}^d}$ of L^2 and making use of the truncated decomposition:

$$g(\mathbf{X}) \simeq \tilde{g}(\mathbf{X}) = \sum_{|\alpha| \leq p} g_{\alpha} \varphi_{\alpha}(\mathbf{X}), \quad g_{\alpha} \in \mathbb{R}^N, \quad \forall \alpha. \quad (1)$$

$\{g_{\alpha}\}$ computation \rightarrow [Blatman and Sudret, 2011].

- Validation of PCE hyperparameters with predictivity coefficient $Q^2 \rightarrow K$ -fold cross-validation.
- Rearranging the coefficients \rightarrow Sobol' sensitivity indices:

$$S_{\gamma}(t_k) = \frac{\sum_{\alpha \in \mathcal{J}_{\gamma}} (g_{\alpha}^k)^2}{\sum_{|\alpha| \leq p} (g_{\alpha}^k)^2}, \quad \forall k \in \{1, \dots, N\}, \gamma \in \mathbb{N}^d. \quad (2)$$

References

- The hierarchy of the influential variables is preserved and similar to what is uncovered in the prior analysis [Lefebvre et al., 2023].
- A new phenomenon discovered is the influence of the clogging porosity ϵ_c in high-pH, high-clogging regime.

- Complementary approach robustifying the Sobol' analysis \rightarrow computation of different HSIC indices.
- Hilbert-Schmidt Independence Criterion (HSIC) [Gretton et al., 2005; Da Veiga, 2015], kernel method \rightarrow evaluates sensitivity of a *single input* in a given-data context.
- Theoretical result for all $i \in \{1, \dots, d\}, k \in \{1, \dots, N\}$:

$$\text{HSIC}(X_i, g_k(X_i)) = 0 \iff X_i \perp g_k(X_i). \quad (3)$$

- The index disposes of U-stat and V-stat estimators that are easily computable in a limited-budget context, and a hypothesis testing with corresponding p -value.
- Moreover, it allows for easy evaluation of local target and conditional indices, for given target regions.

Clogging of steam generators, sensitivity analysis and metamodel validation

Design of experiment
Polynomial chaos expansion (PCE) metamodel

Time-dependent Sobol' indices
Time-varying HSIC indices

Regular HSIC

Target HSIC
Conditional HSIC

GP validation with Conformal Prediction

Summary and upcoming

- The main conclusions from the Sobol' analysis persist, the influential variables are a_v , d_p and $\Gamma_p(0)$ in all chemical conditionings and ϵ_c becomes non-negligible in the high-pH- χ_2 conditioning.

 Time-varying HSIC indices
 Regular HSIC
Target HSIC
 Conditional HSIC

GP validation with Conformal Prediction

Summary and upcoming

- The analysis here provides clear evidence that the clogging porosity becomes the most influential variable in high-clogging, high-pH- χ_2 regime.

- After the preventive cleaning and under high-pH conditions in the χ_2 chemical conditioning, the clogging porosity is visibly the most influential uncertain variable, while the previously dominant variable, d_p , becomes negligible.

- THYC-Puffer-DEPOTHYC is a long-term multiphysics clogging numerical model for SGs developed by EDF R&D in which certain input variables have been exhibited as uncertain.
- Advanced sensitivity analysis tools have been deployed for assessing the influence hierarchy of these different variables and similar results as in [Lefebvre et al., 2023] hold for the long-term clogging model.
- Most notably, the findings related to the influence of the clogging porosity sheds new light on the input-output dependencies and has potential physical interpretations.
- Article submitted for review in the International Journal of Uncertainty Quantification (IJUQ) - GSA Special Issue 2023 [Jaber et al., 2023b].
- Further work would imply developing strategies for performing calibration of the parameter a_v with respect to experimental data.

Conformal Prediction (CP)

- [Vovk et al., 2005; Angelopoulos and Bates, 2023] CP → method for performing UQ on ML algorithms → idea: apply it for metamodel validation.
- For a metamodel \hat{g} , CP provides a way to build *prediction intervals* $\hat{C}_{n,\alpha}$ s.t for a coverage level $1 - \alpha \in (0, 1)$, the *true value of the code* $g(X_{test})$, would be in the set with marginal probability:

$$\mathbb{P}(g(X_{test}) \in \hat{C}_{\alpha,n}(X_{test})) \geq 1 - \alpha, \quad (4)$$

marginal meaning here that it is averaged over any realization of the training DoE.

- Generic method, not many hypothesis → idea: apply it for evaluating GP metamodel robustness → no more Gaussian assumption as with the Bayesian credibility intervals.
